Aspect-Oriented programming with AspectJ

Target audience

 J2EE developers and architects

Objectives

 Get a first look at Aspect-Oriented programming with AspectJ and demonstrate a real-world usage

Non-Objectives

 Learn how to use all features ...

Agenda

- ✍ **AspectJ project**
- ✍ **AOP and AspectJ overview**
 - ✍ problems, basic concepts
- ✍ **AspectJ “tutorial” (in 11 minutes)**
 - ✍ keywords
 - ✍ principles
 - ✍ simple example
- ✍ **Real-life: J2EE-problem concerning transaction rollback when throwing Application Exceptions**
 - ✍ Problem
 - ✍ Solution
 - ✍ Demo
- ✍ **Summary**

<http://www.eclipse.org/aspectj/>

The screenshot shows a Microsoft Internet Explorer browser window displaying the Eclipse Projects website for AspectJ. The browser's address bar shows the URL <http://www.eclipse.org/aspectj/>. The website has a blue header with the Eclipse logo on the left and the text "aspectj" and "crosscutting objects for better modularity" on the right. A left-hand navigation menu includes links for "home...", "eclipse technology...", "AspectJ", "Downloads", "Documentation", "User Resources", "Developer Resources", and "Resources". The main content area features the heading "aspectj project" and two columns of text: "aspectj is" (describing it as a seamless extension to Java) and "aspectj enables" (listing capabilities like error checking and synchronization). Below this are sections for "News" (with a link to a December 18th announcement), "Events" (with a link to the March 17-21, 2003 AOSD Conference), and "Links" (with links to the AJDT Project, AspectJ PARC Page, and AOSD.net). The browser's status bar at the bottom shows "Internet".

AspectJ (v1.0),
Copyright 2003,

good modularity – XML parsing

- ✍ XML parsing in org.apache.tomcat
- ✍ red shows relevant lines of code
- ✍ nicely fits in one box

good modularity – URL pattern matching

- ✍ URL pattern matching in org.apache.tomcat
- ✍ red shows relevant lines of code
- ✍ nicely fits in two boxes (using inheritance)

problems like logging is not modularized

- ✍ where is logging in org.apache.tomcat ?
 - ✍ red shows lines of code that handle logging
 - ✍ not in just one place
 - ✍ not even in a small number of places

the cost of tangled code

✍ **Redundant code**

✍ same fragment of code in many places

✍ **Difficult to reason about**

✍ non-explicit structure

✍ the big picture of the tangling isn't clear

✍ **Difficult to change**

✍ have to find all the code involved

✍ and be sure to change it consistently

✍ and be sure not to break it by accident

✍ **Errors come easy**

✍ Many people involved

✍ **Difficult to test/verify**

✍ Multiple test-cases for the same thing

solution: Crosscutting Concerns

the AOP idea (aspect-oriented programming)

- ✍ **crosscutting is inherent in complex systems**
- ✍ **crosscutting concerns**
 - ✍ have a clear purpose
 - ✍ have a natural structure
 - defined set of methods, module boundary crossings, points of resource utilization, lines of dataflow...
- ✍ **so, let's capture the structure of crosscutting concerns**
explicitly...
 - ✍ in a modular way
 - ✍ with linguistic and tool support
- ✍ **Aspects** are
 - ✍ well-modularized crosscutting concerns

AspectJ™ is...

- ✍ **a small and well-integrated extension to Java**
 - ✍ outputs .class files compatible with any JVM
- ✍ **a general-purpose AO language**
 - ✍ just as Java is a general-purpose OO language
- ✍ **includes IDE support**
 - ✍ emacs, JBuilder, Netbeans, Eclipse
- ✍ **freely available implementation**
 - ✍ compiler is Open Source (Eclipse)
- ✍ **user feedback is driving language design**

basic mechanisms

✍ 1 abstract definition

✍ **joinpoint**

- “points in the execution” of Java programs, method calls

✍ 3 small additions to Java

✍ **pointcut**

- pick out join points and values at those points
 - Method call oriented

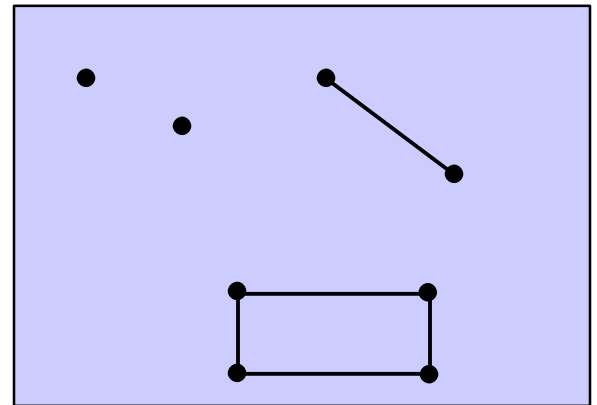

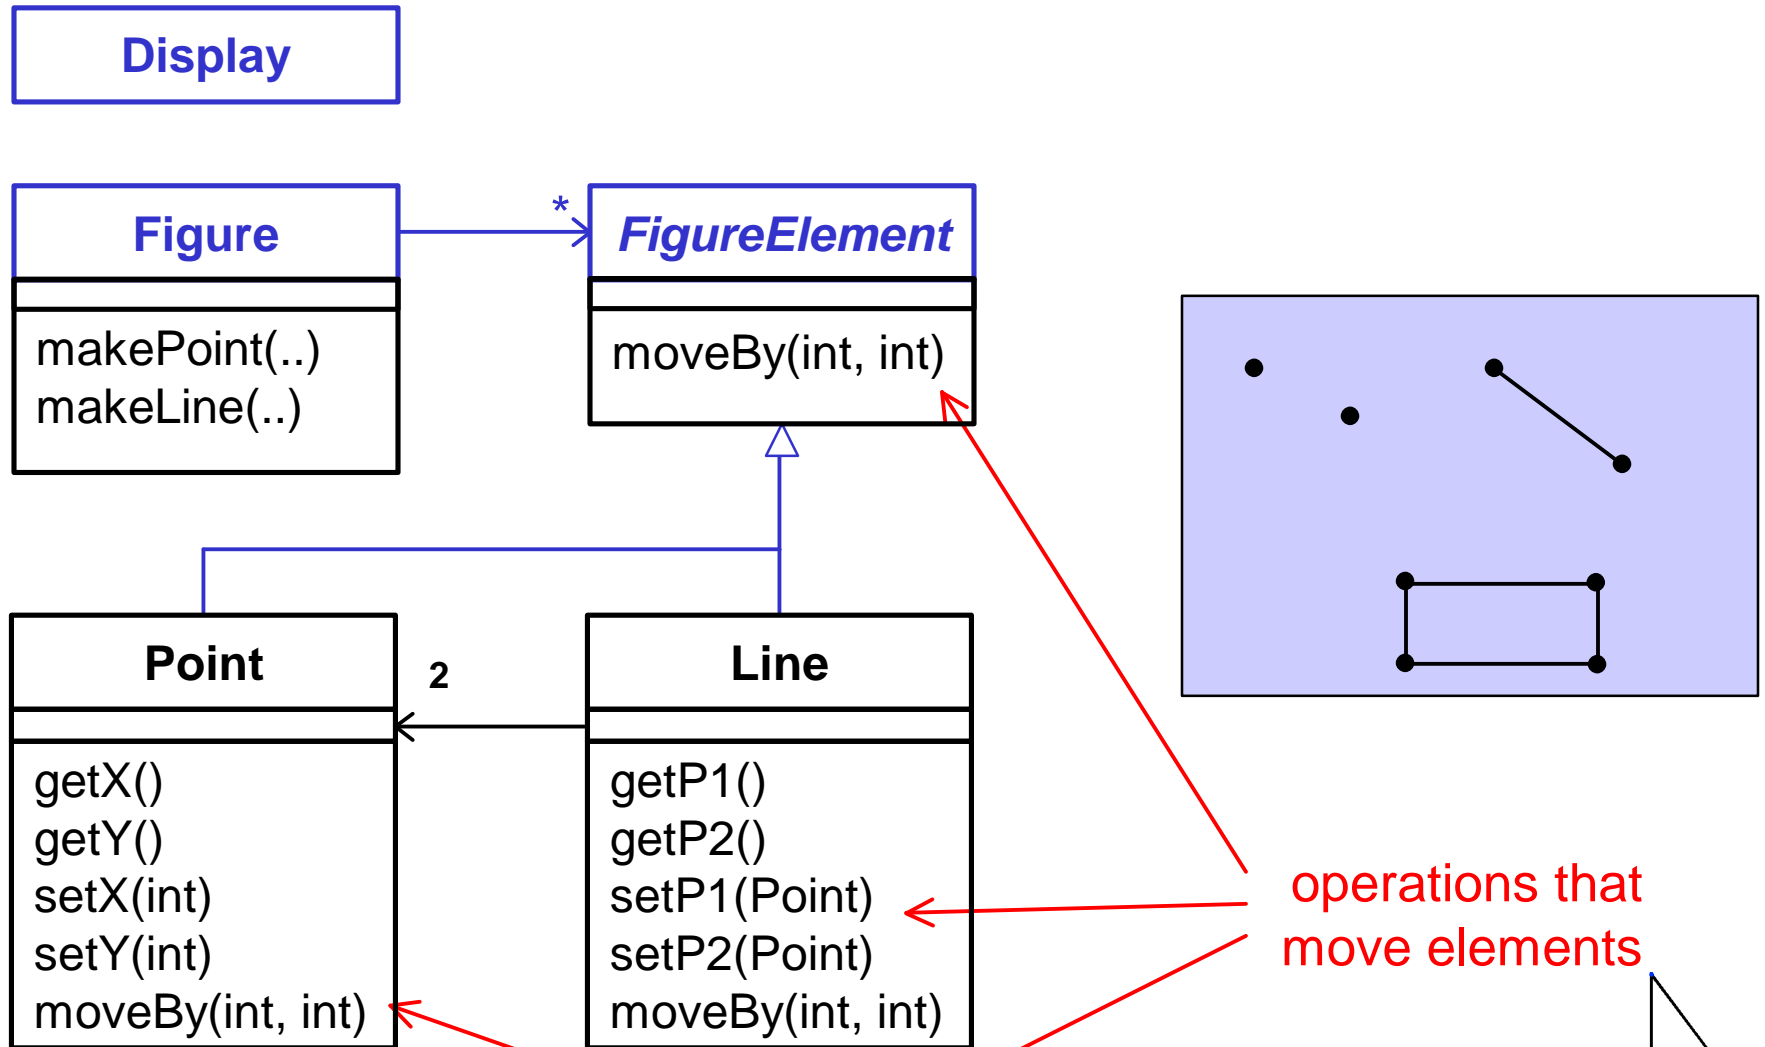

✍ **advice**

- additional action to take at join points in a pointcut

✍ **aspect**

- a modular unit of crosscutting behavior
 - pointcuts (one or many)
 - advice (one or many) for each pointcut
 - Other things (some other time)

a simple figure editor

operations that
move elements

a simple figure editor

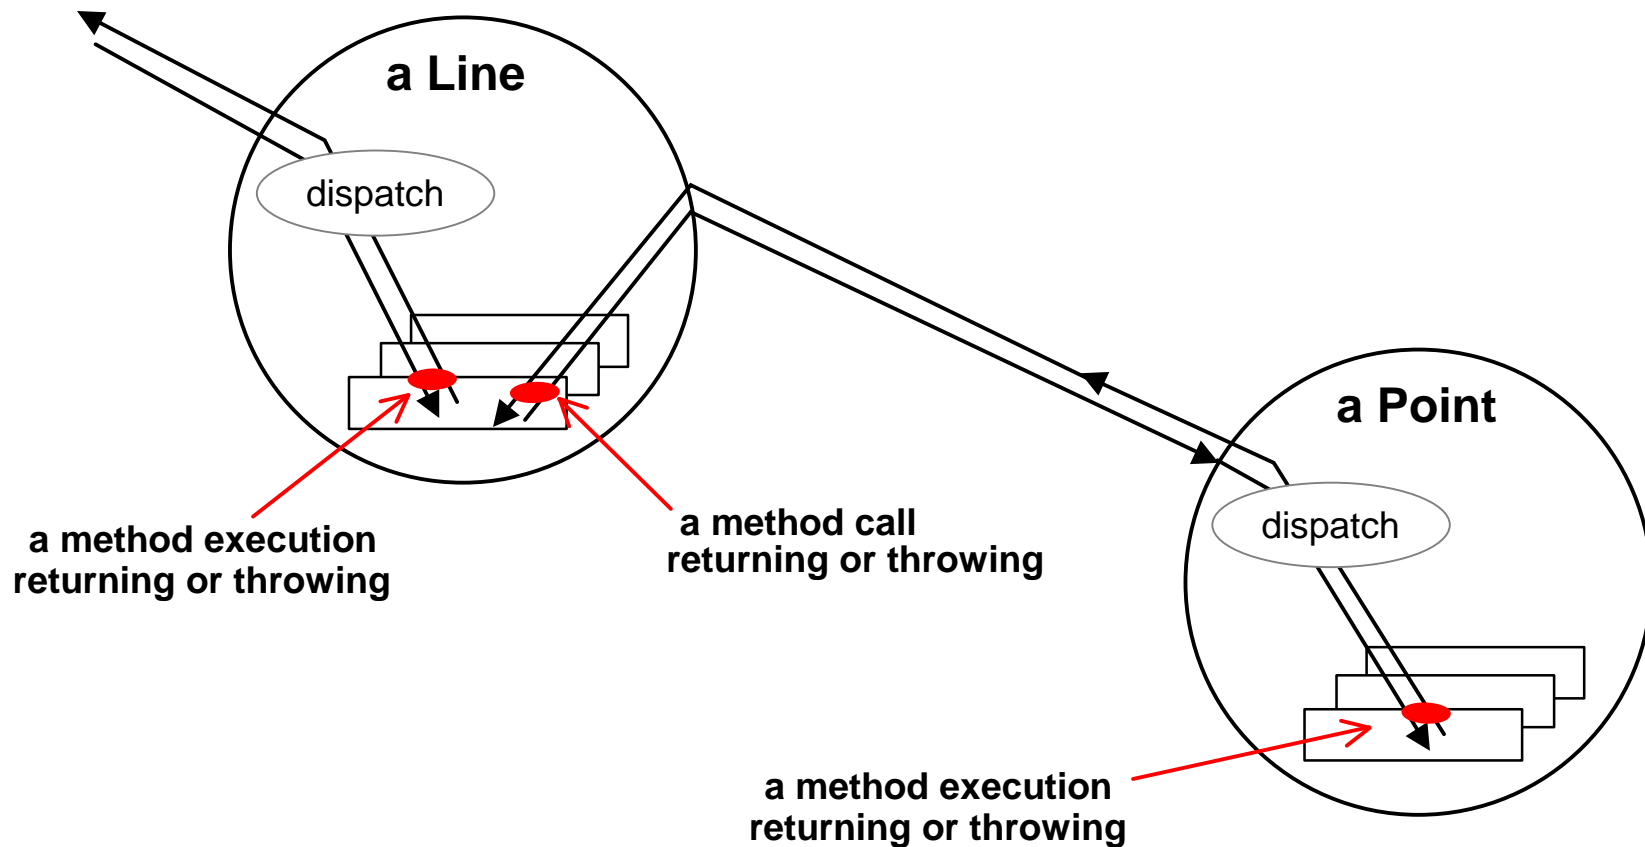

```
class Line implements FigureElement{
    private Point p1, p2;
    Point getP1() { return p1; }
    Point getP2() { return p2; }
    void setP1(Point p1) { this.p1 = p1; }
    void setP2(Point p2) { this.p2 = p2; }
    void moveBy(int dx, int dy) { ... }
}
```

```
class Point implements FigureElement {
    private int x = 0, y = 0;
    int getX() { return x; }
    int getY() { return y; }
    void setX(int x) { this.x = x; }
    void setY(int y) { this.y = y; }
    void moveBy(int dx, int dy) { ... }
}
```

join points - key points in dynamic call graph

imagine `line2.moveBy(2, 2)`

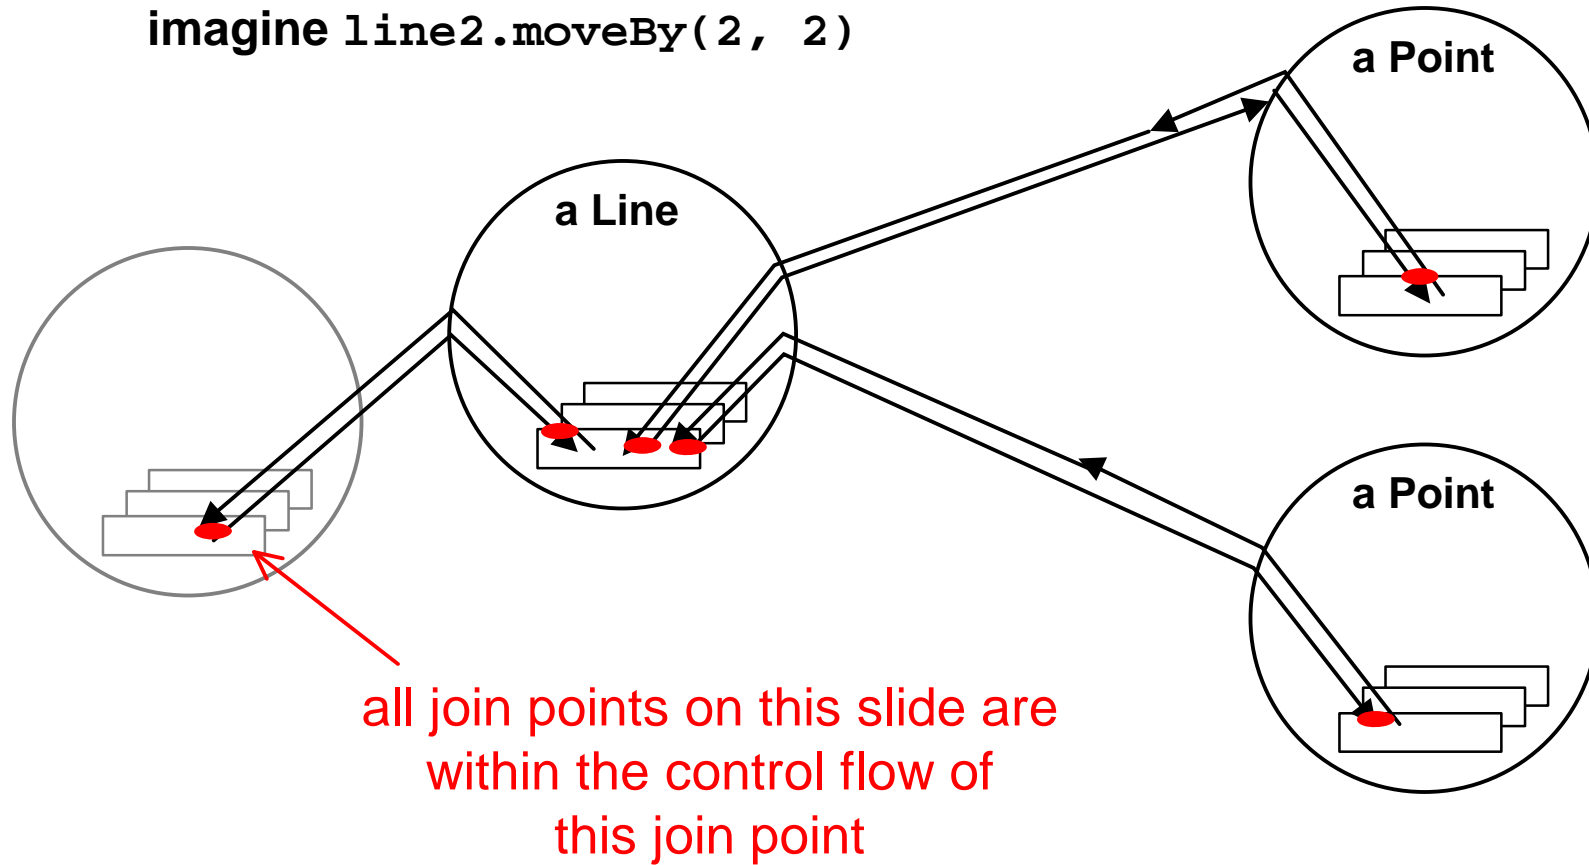

join point terminology

- ✍ several kinds of join points
 - ✍ method & constructor call
 - ✍ method & constructor execution
 - ✍ field get & set
 - ✍ exception handler execution
 - ✍ static & dynamic initialization

join point terminology

imagine `line2.moveBy(2, 2)`

Pointcuts - a means of identifying join points

a pointcut is a kind of predicate on join points that:

- ✍ can match or not match any given join point and
- ✍ optionally, can pull out some of the values at that join point

```
call(void Line.setP1(Point))
```

matches if the join point is a method call with this signature

pointcut composition

pointcuts compose like predicates, using &&, || and !

a “void Line.setP1(Point)” call

```
call(void Line.setP1(Point)) ||  
call(void Line.setP2(Point));
```

← or

a “void Line.setP2(Point)” call

whenever a Line receives a
“void setP1(Point)” or “void setP2(Point)” method call

user-defined pointcuts

user-defined (aka named) pointcuts

✍ can be used in the same way as primitive pointcuts

name

parameters

```
pointcut move():  
    call(void Line.setP1(Point)) ||  
    call(void Line.setP2(Point));
```

after advice - action to take after computation under join points

after advice runs
"on the way back"

```
pointcut move():
```

```
    call(void Line.setP1(Point)) ||  
    call(void Line.setP2(Point));
```

```
after() returning: move() {  
    <code here runs after each move>  
}
```

advice is additional action to take at join points

-  **before** before proceeding at join point
-  **after returning** a value to join point
-  **after throwing** a throwable to join point
-  **after** returning to join point either way
-  **around** on arrival at join point gets explicit control over when&if program proceeds

a simple aspect

an aspect defines something that
can crosscut other classes

```
aspect DisplayUpdating {  
  
    pointcut move():  
        call(void Line.setP1(Point)) ||  
        call(void Line.setP2(Point));  
  
    after() returning: move() {  
        Display.update();  
    }  
}
```

Pointcuts can cut across multiple classes

```
pointcut move():  
    call(void Line.setP1(Point)) ||  
    call(void Line.setP2(Point)) ||  
    call(void Point.setX(int)) ||  
    call(void Point.setY(int));
```

without AspectJ

```
class Line {
    private Point p1, p2;

    Point getP1() { return p1; }
    Point getP2() { return p2; }

    void setP1(Point p1) {
        this.p1 = p1;
        Display.update(this);
    }
    void setP2(Point p2) {
        this.p2 = p2;
        Display.update(this);
    }
}
```

```
class Point {
    private int x = 0, y = 0;

    int getX() { return x; }
    int getY() { return y; }

    void setX(int x) {
        this.x = x;
        Display.update(this);
    }
    void setY(int y) {
        this.y = y;
        Display.update(this);
    }
}
```

- ✍ no locus of “display updating”
- ✍ evolution is cumbersome
- ✍ changes in all classes
- ✍ have to track & change all callers

AB

with AspectJ

```
class Line {
    private Point p1, p2;

    Point getP1() { return p1; }
    Point getP2() { return p2; }

    void setP1(Point p1) {
        this.p1 = p1;
    }
    void setP2(Point p2) {
        this.p2 = p2;
    }
}
```

```
class Point {
    private int x = 0, y = 0;

    int getX() { return x; }
    int getY() { return y; }

    void setX(int x) {
        this.x = x;
    }
    void setY(int y) {
        this.y = y;
    }
}
```

```
aspect DisplayUpdating {

    pointcut move():
        call(void Line.setP1(Point))
        call(void Line.setP2(Point))
        call(void Point.setX(int))
        call(void Point.setY(int));

    after() returning: move() {
        Display.update();
    }
}
```

aspects crosscut classes

Display

aspect modularity cuts across class modularity

EJB Problem

- ✍ Application Exceptions vs. System Exceptions
- ✍ System Exception causes the transaction to rollback (OK)
- ✍ Application Exception must be caught
 - ✍ transaction must be marked for rollback
 - ✍ exception has to be rethrown (problem)
- ✍ Why is this a problem ?
 - ✍ Duplication of boring code
 - ✍ Might be forgotten
 - ✍ Possible inconsistent behavior

Code before refactoring (with aspectj)

```
public void doIt() throws SomeApplicationException,  
                    SomeOtherApplicationException {  
    try {  
        .....  
    }  
    catch ( SomeApplicationException appe1 ) {  
        myContext.setRollbackOnly();  
        throw appe1;  
    }  
    catch ( SomeOtherApplicationException appe2 ) {  
        myContext.setRollbackOnly();  
        throw appe2;  
    }  
}
```

Solution using aspect

Prereqs

-  All ejb:s belong to one or a few packages (ok)
-  All Application Exceptions has common base class (ok)
-  All Bean classes must implement one extra interface containing getSessionContext().
 - SessionBean only contains setSessionContext()
 - workaround but method is already there

aspect

```
public aspect RollbackApplicationExceptions {
```

```
    pointcut ejbRemoteMethodCall(ejb.RollbackableEJBBean bean):
```

```
        call(public * ejb..*Bean.* (..) )
        && !call(public * ejb..*Bean.ejb* (..) )
        && !call(public * ejb..*Bean.*SessionContext(..))
        && !call(public * ejb..EJS*.* (..))
        && target(bean);
```

```
    pointcut topLevelCall(ejb.RollbackableEJBBean bean):
```

```
        ejbRemoteMethodCall(bean)
        && !cflowbelow(ejbRemoteMethodCall(bean));
```

```
    after(ejb.RollbackableEJBBean bean)
```

```
        throwing (api.ApplicationException appe):
        topLevelCall(bean) {
        bean.getSessionContext().setRollbackOnly();
```

```
    }
```

```
}
```

Demo

- ✍ EJB-bean without rollback call
- ✍ EJB method
 - ✍ Insert a line in a DB table
 - ✍ Throws an Application Exception
- ✍ TestCase - assert (row count after == row count before)
- ✍ Junit/Cactus to run test

Where is AOP in the big picture ?

- ✍ 3GL
- ✍ (4GL) dead end street ?
- ✍ OO
- ✍ AO

» or

- ✍ OO
 - All Objects depend on each other
 - Components
 - Service-based interfaces - DTO
 - Model-driven
 - Design patterns
 - AO

Development environment

- ✍ Handcrafted code – big save
- ✍ Frameworks – depends
- ✍ Code generators – depends

Is AspectJ ready to use ?

- ✍ AOP competition: Hyper/J, frameworks etc.
- ✍ Ver 1.1 promises (beta is available)
 - ✍ Incremental compiler
 - ✍ Better intergation with eclipse (other IDE's are moved to source-forge)
- ✍ The debate is on
